Nationwide Frequency and Costs of Potentially Preventable Hospitalizations, 2006

H. Joanna Jiang, Ph.D., C. Allison Russo, M.P.H., and Marguerite L. Barrett, M.S.

Introduction

Hospital care represents the largest component of overall health care expenditures.¹ Some hospitalizations can be potentially prevented with timely and effective ambulatory care. High admission rates for these potentially preventable conditions may indicate a need for improvements in access to ambulatory care and in the quality of care provided, as well as in patient adoption of healthy lifestyles and active self-management of chronic conditions. Thus, reducing the frequency of potentially preventable hospitalizations would be an effective strategy for lowering costs while improving quality of care and patient outcomes.²

This Statistical Brief presents national data from the Healthcare Cost and Utilization Project (HCUP) on rates and total costs of potentially preventable hospitalizations. Distribution of the total costs by payer is also examined. Lastly, comparisons of potentially preventable hospitalization rates by median income level of patient’s ZIP Code are presented. The Agency for Healthcare Research and Quality (AHRQ)’s Prevention Quality Indicators (PQIs)³ are used to identify hospitalizations for select chronic and acute conditions in adults and children for 2006. All differences between estimates noted in the text are statistically significant at the 0.05 level or better.

Findings

In 2006, nearly 4.4 million hospital admissions, totaling $30.8 billion in hospital costs, could have been potentially preventable with timely and effective ambulatory care or adequate patient self-

---

²To better assist health care decision makers in implementing this strategy, AHRQ has developed a tool for mapping the frequency of potentially preventable hospitalization for a state, by county, and estimating the cost savings associated with reducing the level of these hospitalizations. http://www.qualityindicators.ahrq.gov/mappingtool.htm
management of the condition. Hospital costs for potentially preventable hospitalizations represented about one of every 10 dollars of total hospital expenditures in 2006. Compared to 2004, there was no substantial change in the total number of admissions or total hospital costs for these potentially preventable conditions.4

_Potentially preventable hospitalizations among adults and children_
Table 1 displays the number of admissions and total hospital costs for potentially preventable conditions among adults and children. There were nearly 4.1 million admissions (1,825 admissions per 100,000 population) for potentially preventable conditions among adults, which totaled $30.1 billion in hospital costs. Children accounted for about 276,000 potentially preventable hospitalizations, totaling $737 million in hospital costs.

Congestive heart failure and bacterial pneumonia were the two most common reasons for potentially preventable hospitalizations. Together, they contributed to half of the total hospital costs ($8.4 billion and $7.2 billion, respectively) for all potentially preventable hospitalizations. Among children, pediatric asthma was the most costly potentially preventable condition ($293 million), but pediatric gastroenteritis accounted for the highest number of potentially preventable hospitalizations (133 million admissions, or 183 admissions per 100,000 population).

_Share of total hospital costs by expected primary payer_
Figure 1 compares the distribution of total hospital costs by payer between potentially preventable hospitalizations and all other non-obstetric hospitalizations. Among adults, Medicare patients contributed to 67 percent ($20.1 billion) of the total hospital costs for potentially preventable hospitalizations, which is much higher than the 50 percent share of total hospital costs for all other non-obstetric hospitalizations. In fact, potentially preventable conditions accounted for nearly one in five (18 percent) non-obstetric Medicare admissions—significantly higher than the percentage for any other payer (figure 2).

In contrast, patients with private insurance accounted for only 16 percent ($4.7 billion) of the total cost for potentially preventable admissions, as compared to 30 percent of the hospital costs for all other non-obstetric admissions. As shown in figure 2, only 7 percent of all privately insured admissions were for potentially preventable conditions—nearly half the percentage for all payers combined (13 percent).

The percent of total hospital costs attributable to patients with Medicaid and the uninsured was similar between potentially preventable hospital stays and all other non-obstetric hospitalizations (11 percent versus 12 percent for Medicaid patients, and 5 percent versus 5 percent for the uninsured). However, 12 percent of uninsured hospitalizations were potentially preventable, significantly higher than the 9 percent of Medicaid hospitalizations.

_Differences in preventable hospitalization rates by community income level_
Table 2 compares the admission rate for potentially preventable conditions by community income level. Patients living in the poorest communities (the lowest median income quartile) were disproportionately more likely than those living in the wealthiest communities (the highest median income quartile) to be hospitalized with a potentially preventable condition. The difference in admission rates between the poorest and wealthiest communities ranged from 130 percent to more than 400 percent across individual diseases.

These disparities in admission rates were especially evident for chronic conditions, where potentially preventable admission rates in the poorest communities were two to four times higher than those in the wealthiest communities. The disparity in admission rates was highest for diabetes without complications: patients from the poorest communities were hospitalized at a rate of 41.4 admissions per 100,000 populations—4.2 times higher than the admission rate for this condition in the wealthiest communities.

Similarly, patients from the poorest communities were hospitalized for diabetes with short-term complications at a rate of 91.6 admissions per 100,000 population, which was 2.7 times higher than the admission rate in wealthier communities. However, this variation was markedly lower for acute conditions, where admission rates in the poorest communities were 30 to 60 percent higher than those in the wealthiest communities.

Data Source

The estimates in this Statistical Brief are based upon data from 2006 Nationwide Inpatient Sample (NIS). Population bases for rates were obtained from Claritas, a vendor that compiles data from the U.S. Census Bureau. Claritas uses intercensal methods to estimate population subgroups.

Definitions

Types of hospitals included in HCUP
HCUP is based on data from community hospitals, defined as short-term, non-Federal, general and other hospitals, excluding hospital units of other institutions (e.g., prisons). HCUP data include OB-GYN, ENT, orthopedic, cancer, pediatric, public, and academic medical hospitals. They exclude long-term care, rehabilitation, psychiatric, and alcoholism and chemical dependency hospitals, but these types of discharges are included if they are from community hospitals.

Unit of analysis
The unit of analysis is the hospital discharge (i.e., the hospital stay), not a person or patient. This means that a person who is admitted to the hospital multiple times in one year will be counted each time as a separate "discharge" from the hospital.

Prevention Quality Indicators
The Prevention Quality Indicators (PQIs) are part of a set of AHRQ Quality Indicators (QIs) developed by investigators at Stanford University and the University of California under a contract with AHRQ. The PQIs are a set of measures that can be used with hospital inpatient discharge data to identify quality of care for "ambulatory care-sensitive conditions." These are conditions for which good outpatient care can potentially prevent the need for hospitalization or for which early intervention can prevent complications or more severe disease. PQI rates can also be affected by other factors, such as disease prevalence.

Further information on the AHRQ QIs, including documentation and free software downloads, is available at http://www.qualityindicators.ahrq.gov. This Web site includes information on the newest version of the PQIs, Version 3.2.

Diagnoses and ICD-9-CM
PQI admission rates are based on principal diagnosis for all measures except diabetes-related lower-extremity amputations. For this PQI, counts are included in the numerator if the condition of interest is indicated in any diagnosis field. The principal diagnosis is that condition established after study to be chiefly responsible for the patient's admission to the hospital. Secondary diagnoses are concomitant conditions that coexist at the time of admission or that develop during the stay. All-listed diagnoses include the principal diagnosis plus these additional secondary conditions.

ICD-9-CM is the International Classification of Diseases, Ninth Revision, Clinical Modification, which assigns numeric codes to diagnoses. There are about 12,000 ICD-9-CM diagnosis codes.

Populations for calculating admission rates
The populations used to calculate admission rates vary by type of condition. PQIs for adult diabetes, circulatory diseases, chronic respiratory diseases, and acute diseases include individuals 18 years and older. Pediatric short-term diabetes complications include children between 6 and 17 years of age; pediatric asthma includes children between 2 and 17 years of age; and pediatric gastroenteritis and bacterial pneumonia include children ages 3 months to 17 years. Denominator populations for all PQIs in
this Brief are derived from Claritas year-specific U.S. population data. All PQIs are adjusted for age and gender using the total U.S. population for the year 2000 as the standard population.

**Costs and charges**
Total hospital charges were converted to costs using HCUP Cost-to-Charge Ratios based on hospital accounting reports from the Centers for Medicare and Medicaid Services (CMS).\(^5\) Costs will tend to reflect the actual costs of production, while charges represent what the hospital billed for the case. For each hospital, a hospital-wide cost-to-charge ratio is used because detailed charges are not available across all HCUP States. Hospital charges reflect the amount the hospital charged for the entire hospital stay and does not include professional (physician) fees. For the purposes of this Statistical Brief, costs are reported to the nearest hundred.

**Median community income level**
Median community income level is the median household income of the patient's ZIP Code of residence. The cut-offs for the quartile designation is determined using ZIP Code demographic data obtained from Claritas. The income quartile value is missing for homeless and foreign patients.

**Payer**
Payer is the expected primary payer for the hospital stay. To make coding uniform across all HCUP data sources, payer combines detailed categories into more general groups:

- Medicare includes fee-for-service and managed care Medicare patients.
- Medicaid includes fee-for-service and managed care Medicaid patients. Patients covered by the State Children's Health Insurance Program (SCHIP) may be included here. Because most state data do not identify SCHIP patients specifically, it is not possible to present this information separately.
- Private insurance includes Blue Cross, commercial carriers, and private HMOs and PPOs.
- Other includes Worker's Compensation, TRICARE/CHAMPUS, CHAMPVA, Title V, and other government programs.
- Uninsured includes an insurance status of "self-pay" and "no charge."

When more than one payer is listed for a hospital discharge, the first-listed payer is used.

**About HCUP**
HCUP is a family of powerful health care databases, software tools, and products for advancing research. Sponsored by the Agency for Healthcare Research and Quality (AHRQ), HCUP includes the largest all-payer encounter-level collection of longitudinal health care data (inpatient, ambulatory surgery, and emergency department) in the United States, beginning in 1988. HCUP is a Federal-State-Industry Partnership that brings together the data collection efforts of many organizations—such as State data organizations, hospital associations, private data organizations, and the Federal government—to create a national information resource.

HCUP would not be possible without the contributions of the following data collection Partners from across the United States:

**Arizona** Department of Health Services  
**Arkansas** Department of Health  
**California** Office of Statewide Health Planning and Development  
**Colorado** Hospital Association  
**Connecticut** Hospital Association  
**Florida** Agency for Health Care Administration

About the NIS

The HCUP Nationwide Inpatient Sample (NIS) is a nationwide database of hospital inpatient stays. The NIS is nationally representative of all community hospitals (i.e., short-term, non-Federal, non-rehabilitation hospitals). The NIS is a sample of hospitals and includes all patients from each hospital, regardless of payer. It is drawn from a sampling frame that contains hospitals comprising about 90 percent of all discharges in the United States. The vast size of the NIS allows the study of topics at both the national and regional levels for specific subgroups of patients. In addition, NIS data are standardized across years to facilitate ease of use.

For More Information

For more information about HCUP, visit www.hcup-us.ahrq.gov.

For additional HCUP statistics, visit HCUPnet, our interactive query system, at www.hcup.ahrq.gov.

For a detailed description of HCUP, more information on the design of the NIS, and methods to calculate estimates, please refer to the following publications:

*aThe total for adults excludes those lower extremity amputations that are also reported under short-term or long-term diabetes complications, as to avoid double counting.

*bDue to differences in the age criterion for individual pediatric conditions, the total number of admissions per 100,000 children is not estimated.
